Large cell neuroendocrine carcinoma of the larynx: A case report

Neuroendocrine carcinoma of the head and neck is a very rare tumor. The parotid gland is the site most commonly affected. Squamous cell carcinoma of the larynx is the most common form of laryngeal cancer (85 to 90% of cases. The other histological forms are exceptional, and represent only about 2 to 3% of all malignant tumors of the larynx.

We report a case of an 86-year-old patient who consulted for dysphagia in solids and liquids. Radiological and endoscopic investigation found a locally advanced Neuroendocrine carcinoma of the larynx. Patient was operated, and had an adjuvant radiotherapy.
